• Phenomenology of Pure GGM for LHC @ 7 TeV
“Normal” gauge mediation:

\[ (f \cdot \tilde{f}) \Phi = (f \cdot \tilde{f})(M + \theta^2 F) \]

Universal form for gaugino and sfermion masses - of same order
Direct gauge mediation:

SUSY breaking dynamics now important; can have much smaller gaugino masses

Poppitz Trivedi (1996) ....
Izawa, Momura, Tobe, Yanagida (1997)
Csaki, Shirman, Terning (2006)
Kitano Ooguri Ookouchi (2006)
SAA, Durnford, Jaeckel, Khoze (2007)
SAA, Jaeckel, Khoze, Matos (2008)
General approach:

- Adopt the GGM assumption of Meade, Seiberg and Shih: defined by the requirement that the MSSM becomes decoupled from SUSY breaking sector when \( \alpha_1 = \alpha_2 = \alpha_3 = 0 \)

- They showed that the possible patterns of SUSY breaking (in the MSSM) can be completely determined by 6 combinations of gauge current correlators.

- But what patterns are likely?

- And what underlying physics is associated with each pattern?

Objective: strategy for GMSB pheno at early LHC
Outline

- GGM definition and motivation
- DSB (metastable) and two general theorems
- Phenomenology of Pure GGM for LHC @ 7 TeV
DSB (metastable)

ISS model (2006) inspired much of the current interest  (Intriligator Seiberg Shih)

Universe sits here

vacuum is supersymmetric
Nelson-Seiberg Th’m

The origin is metastable because of an *anomalous* R-symmetry

\[
W^{ISS} = W_{cl} + W_{dyn}
\]

*In a generic theory SUSY breaking requires an R-symmetry* (Nelson, Seiberg)

But: gaugino mass terms \( M_{\lambda} \lambda^{\alpha} \lambda_{\alpha} \) always have non-zero R-charge

So: non-zero gaugino masses require both R-symmetry and SUSY breaking \( \rightarrow \) R-symmetry breaking!
Two possible options (NB - the anomalous R-breaking can’t give gaugino masses):

1) Explicit R-breaking

\[ W = W_{R-sym} + \varepsilon W_{R-breaking} \]

a global SUSY minimum develops \( \mathcal{O}(1/\varepsilon^{\text{power}}) \) away in field space

\[ M_\lambda \propto \varepsilon^{\text{power}'} \]

2) Spontaneous R-breaking (or a combination of explicit + spontaneous)
Explicit Breaking example

Murayama and Nomura 2007

How to break an R-breaking gaugino mass without destabilising vacuum? ISS is based on electric/magnetic Seiberg duals - suppose the messenger sector breaks R-symmetry maximally in the electric theory:

\[ W_{cl} = W_{cl}^{ISS} + \frac{\lambda}{M_{Pl}} Q \tilde{Q} f \tilde{f} + M f \tilde{f} \]

\[ W_{cl} = W_{cl}^{ISS} + \frac{\lambda \Lambda}{M_{Pl}} \Phi f \tilde{f} + M f \tilde{f} \]
Explicit Breaking example

Murayama and Nomura 2007

How to break an R-breaking gaugino mass without destabilising vacuum? ISS is based on electric/magnetic Seiberg duals - suppose the messenger sector breaks R-symmetry maximally in the electric theory:

\[ W_{cl} = W_{cl}^{ISS} + \frac{\lambda}{M_{Pl}} Q \tilde{Q} f \tilde{f} + M f \tilde{f} \]

\[ W_{cl} = W_{cl}^{ISS} + \left( \frac{\lambda \Lambda}{M_{Pl}} \right) \Phi f \tilde{f} + M f \tilde{f} \]

\[ := \varepsilon \]
Thanks to Nelson-Seiberg, a new lower vacuum appears but far away ...

The model generates gaugino and scalar masses of the same order - but you have to be reasonably careful to avoid vacuum decay.
Spontaneous Breaking example

Can simply “deform” ISS for direct gauge mediation \textnormal{(SAA, Durnford, Jaeckel, Khoze)}

\[ W_{cl} = W_{cl}^{ISS} + m \varepsilon_{ab} \varepsilon^{rs} q^a_r q^b_s \]

where \( r, s = 1, 2 \) are the 1st and 2nd “flavour” numbers.
and \( a, b = 1, 2 \) are gauge indices.
Gauge the remaining 5 flavours: \( SU(5)_f \supset G_{SM} \)

Because of the deformation \( \Phi \) develops a VEV, and R-is broken.
Spontaneous Breaking example

The mediators are $q_\alpha^i = 1..5$ and $\tilde{q}_a^i = 1..5$ and the typical scalar mass is

$$m_{scalar} \sim \frac{g_A^2}{16\pi^2}\mu_2$$

But ... this is a model of ‘slightly split SUSY’ - gaugino masses are zero at tree-level. Typically suppressed by a factor of a few * 10 (similar to the effect found by Izawa, Momura, Tobe, Yanagida in 1997)
Why? Komargodski and Shih Th’m

If there is a non-zero gaugino mass at leading order then there will be some value of pseudo-Goldstone mode (i.e. $\langle \Phi \rangle$) with tachyonic messengers.

Non-zero gaugino masses require a lower lying vacuum at some point in moduli space, at tree-level (note that the basic ISS model does not have this).
Simplest way to see this in action: bring in a lower lying vacuum from infinity by having explicit R-breaking messenger:

$$W_{cl} = W_{cl}^{ISS} + W^{deform} + W^{MN}$$
Hybrid model
(SAA, Jaeckel, Khoze)

At leading order gaugino masses from explicit f-messengers only, but scalars from both q and f-messengers.

\[
\frac{M_{gaugino}^2}{m_{scalar}^2} \sim N_f \cdot \frac{1}{1 + \frac{N_q}{N_f} \left( \frac{M_f}{\lambda \mu_5} \right)^2}
\]

The distance away in field space of the lower vacuum is \( \Phi \sim M_f / \lambda \)

As this is brought in from infinity, the SUSY breaking goes from being infinitely split to standard \( \sim 1 \).
Outline

• GGM definition and motivation
• DSB (metastable), two models and two general theorems
• Phenomenology of Pure GGM for LHC @ 7 TeV

“Pure” means no additional generation of Higgs “B term”. This must be generated radiatively -> large tan beta (Rattazzi, Sarid; Gabrielli Sarid)
General set-up for phenomenological study

Take Pure GGM parameter space and restrict to single effective scale for the gaugino masses and for the scalar masses

- includes any scenario with preserved GUT structure in mediation
- captures the main effects of R-symmetry and metastability
- is equivalent to \( m_0, m_1/2 \) in CMSSM
- in contrast with other work (e.g. Carpenter; Rajaraman, Shirman, Smidt, Yu)

\[
\begin{align*}
M_{\tilde{\chi}_i}(M_{mess}) &= k_i \frac{\alpha_i(M_{mess})}{4\pi} \Lambda_G \\
m_f^2(M_{mess}) &= 2 \sum_{i=1}^{3} C_i k_i \frac{\alpha_i^2(M_{mess})}{(4\pi)^2} \Lambda_S^2
\end{align*}
\]

where C’s are quadratic Casimir operators of gauge groups, \( k_i = (5/3, 1, 1) \) and \( k_i \alpha_i \) are equal at the GUT scale.
B and tan beta at low energy

e.g. take intermediate messenger scale: $M_{mess} = 10^{10}$ GeV  

\(\text{SoftSUSY: Allanach}\)
B and tan beta at low energy

e.g. take intermediate messenger scale: \( M_{mess} = 10^{10} \text{ GeV} \)

Direct mediation with spontaneous R-breaking

Standard gauge mediation line
Fine tuning

Dominated by scalar masses which decrease when either $\Lambda_G$ or $\Lambda_S$ decrease. So starting at the line of standard gauge mediation and going to the split scenario by decreasing $\Lambda_G$ does not increase tuning.
Experimental constraints

To compare with Normal Gauge mediation, look at general scalar and gaugino masses in gauge mediation and apply experimental bounds ...

Experimental constraints

Fit doesn’t favour degenerate SUSY breaking for scalars and gauginos

\[ \text{messenger scale} = 10^{10} \]

\[ \text{messenger scale} = 10^{14} \]
NLSP

The NLSP can eventually decay to the LSP (the gravitino)

• Neutralino: displaced vertex with decay to photon ($\chi_1^0 \rightarrow \tilde{G}\gamma$) or jet/lepton pairs ($\chi_1^0 \rightarrow \tilde{G}Z \rightarrow \tilde{G} + jets/l\bar{l}$)

• Stau: displaced vertex with ionization track and decay predominantly to jets ($\tilde{\tau}_R \rightarrow \tilde{G}\tau \rightarrow \tilde{G}\nu_\tau + jets/l\bar{l}$)

• Co-NLSP: neutralino/stau mass difference less than tau-mass - mix of two
The NLSP is either neutralino or stau or co-NLSP

![Diagram showing the NLSP regions in the \( \Lambda_G, \Lambda_S \) parameter space for two different values of \( M_{\text{mess}} \). The NLSP is \( \chi_0^1 \) in the green region, \( \chi_0^1/\tilde{\tau} \) co-NLSP in the red region, and \( \tilde{\tau} \) in the blue region.]

\[ \log_{10}(G (\text{GeV})) \]

\[ \log_{10}(S (\text{GeV})) \]
Decay inside detector?

(Bagger Matchev Pierce Zhang)

\[ k_G^2 L_{\text{decay}} = \frac{1}{\kappa} \left( \frac{100 \text{GeV}}{m_{NLSP}} \right)^5 \left( \frac{\sqrt{\Lambda G M_{\text{mess}}}}{100 \text{TeV}} \right)^4 0.1 \text{ mm} \]

where \( \kappa \) is of order one (mixing in NLSP) and \( k_G \) is the effective number of messengers to the gaugino \( (\Lambda_G = k_G F_0 / M_{\text{mess}}) \)
Benchmark points

Decays of gluino:

(SUSY-HIT: Djouadi Muehlleitner Spira)
Summary

- Direct, indirect and hybrid scenarios can cover much of available gauge mediation parameter space - including ordinary and mildly split

- A strategy for phenomenology that captures the effects of the vacuum structure is to analyse in $\Lambda_S, \Lambda_G$ parameter space.

- Pure General Gauge Mediation phenomenology is accessible at 7TeV in a number of interesting scenarios

- Light gluino (with neutralino NLSP), stau-NLSP and co-NLSP phenomenology

- SLHA data for benchmark points at http://www.ippp.dur.ac.uk/~SUSY
